0.2 Linear Mixed Effects Model: analyze data with repeated measures

- Each participant has multiple trials, so the trials within a participant are likely correlated
- Data is nested
- Each participant may have their own baseline level of emotional responses
- fixed effects (trial.val, sex, age, ethn) explain the variation between individuals
- random effects (1|subj) explain the correlation of repeated measures within individuals

0.2.1 How different trial types & demographics affect negative emotional response (Ineg)?

```

```

- Random effects: each participant has a different baseline emotional response
 - (1|subj): represents the random effect
 - * each participant (subj) has a different baseline deviation (intercept).
 - * This accounts for the correlation between multiple trial results from the same participant
- REML score (residual maximum likelihood estimate): assess the model fit
- Fixed Effects:
 - Intercept: Negative trial
 - trial.valneu (Neutral trial): Estimate = -4.08, t = -118.57, a very significant negative value.
 - * Compared to the baseline (negative trial), the neutral trial significantly decreases negative emotions (Ineg)
 - trial.valpos (Positive trial): Estimate = -4.09, t = -168.08, also significant.
 - \ast the positive trial also significantly decreases negative emotions compared to the negative trial
 - sexfemale: Estimate = 0.317543, t = 2.606.
 - * Females have significantly higher negative emotional responses (Ineg) compared to
 - The effects of age and ethnicity are small and not significant

0.2.2 How different trial types & demographics affect positive emotional response (Ipos)?

```
# Mixed-effects model for predicting Ipos

```

- Intercept (negative trial): estimate = 2.93, t-value = 3.84. The effect of negative trial on arousal (Iaro) is moderate.
- trial.valneu: estimate -2.26, t-value = -64.28. Compared to valneg, the neutral trial significantly decreases arousal (Iaro), which can be expected.
- trial.valpos: estimate = -0.30, t-value = -12.10. Compared to valneg, the positive trial also significantly decreases arousal (Iaro), but the effect is small.
- Other fixed effects are not significant.

```

Inertia scores that are not normal:

- neg_inertia_pos: normality_p = 6.689087e-10; skewness = 1.07982750
 - Under positive stimuli, negative emotion inertia is right-skewed: a few individuals have unusually persistent negative emotions
- pos_inertia_neg: normality_p = 2.318693e-09; skewness = 1.27067898
 - Under negative stimuli, positive emotion inertia is strongly right-skewed: most people have low inertia in positive feelings, with a few showing strong inertia
- pos_inertia_neu: normality_p = 8.436415e-08; skewness = -0.39896752
 - For neutral stimuli, positive emotion inertia is slightly left-skewed
- neg_inertia_neu: normality_p = 1.296106e-07; skewness = 1.29575508
 - For neutral stimuli, negative emotion inertia is strongly right-skewed
- aro inertia neu: normality p = 3.859573e-05; skewness = 0.71497318
 - For neutral stimuli, arousal inertia is right-skewed

0.3.1 Normalize the skewed inertia types

```
# Transform the skewed inertia types to normal
library(bestNormalize)

skewed_vars <- c(
    "neg_inertia_pos", "pos_inertia_neg", "pos_inertia_neu",
    "neg_inertia_neu", "aro_inertia_neu"
)

inertia_long_normalized <- inertia_long %>%
    group_by(inertia_type) %>%
```

```
mutate(
    inertia_trans = if_else(
     inertia type %in% skewed vars,
     orderNorm(inertia)$x.t, # transform only these
     inertia # leave others unchanged
   )
 )
## Warning: There were 6 warnings in 'mutate()'.
## The first warning was:
## i In argument: 'inertia_trans = if_else(...)'.
## i In group 3: 'inertia type = "aro inertia neu"'.
## Caused by warning in 'orderNorm()':
##! Ties in data, Normal distribution not guaranteed
## i Run 'dplyr::last_dplyr_warnings()' to see the 5 remaining warnings.

```

- aro_inertia_neu: Extremely high SD (0.998) suggests arousal inertia under neutral stimuli varies greatly across individuals
- neg_inertia (mean = -0.024): Negative emotion inertia is slightly negative, meaning negative emotion is not likely to last
- neg_inertia_pos: Negative near-zero mean (-9.32e-06) but very high variance (sd = 0.999);
 - Negative emotion is likely to bounce back after positive stimuli, but the effect is extremely small
 - There's huge individual differences
- pos_inertia_neg: Negative near-zero mean (-3.28e-05) but very high variance (sd = 0.999);
 - Positive emotion is likely to bounce back after negative stimuli, but the effect is also small
 - There's huge individual differences
- pos_inertia (mean = -0.032): negative mean indicates that positive emotions tend to drop off quickly
- aro_inertia_neg (mean = 0.031): clear positive inertia arousal tends to linger more after negative stimuli
- neg inertia neg (mean = 0.024): negative emotions tend to persist more after negative trials
- neg inertia (mean = -0.024) vs. pos inertia (mean = -0.032):
 - neg_inertia is bigger than pos_inertia, meaning that negative emotions tend to last longer

- Positive emotions bounce back faster than negative emotions
- $neg_inertia_pos (mean = -9.32e-06) vs. pos_inertia_neg (-3.28e-05)$:
 - Emotions tend to reset quickly when the stimulus is the opposite, meaning that people are likely to be affected by opposite stimuli
 - Positive emotions may dissipate faster in response to negative stimuli than negative emotions do in response to positive ones (positive emotion is more likely to be affected by negative stimuli)
- 0.3.3 Compare emotional inertia types (pos_inertia, neg_inertia, aro_inertia) by demographics

```
# Pivot transformed inertia data to wide format

inertia_wide_trans <- inertia_long_normalized %>%
    select(subj, inertia_type, inertia_trans) %>%
    tidyr::pivot_wider(
    names_from = inertia_type,
    values_from = inertia_trans
)

# Extract demographic info from your original dat

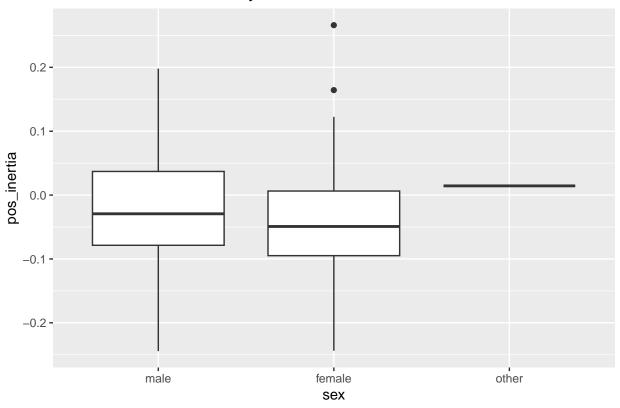

demo_info <- dat %>%
    select(subj, sex, age, ethn) %>%
    distinct()

# Merge the transformed inertia data with demographics
inertia_full <- inertia_wide_trans %>%
    left_join(demo_info, by = "subj")

 labs(title = "Positive Emotion Inertia by Sex")
```

Positive Emotion Inertia by Sex

- Females have much lower positive inertia (-0.043) than males (-0.021) -> quicker drop in positive feelings
- Females have higher arousal inertia (0.019) than males (-0.011) -> more sustained arousal
- It's surprising that neg_inertia is about the same for male and female, considering that females are twice as likely as males to get depression based on reports

```
# By ethnicity

                                                                             0.00867
```

## 2 Black/African American	0.00711	-0.0267	-0.00710
## 3 Latino/Hispanic	-0.0172	-0.0306	0.00750
## 4 Other	-0.0102	-0.0207	0.0640
## 5 White/Caucasian	-0.0373	-0.0327	-0.00488
## 6 American Indian/Native American or Alaska~	-0.0393	0.0856	0.0272
## 7 Decline to state	-0.0831	0.00606	0.0983

- American Indian/Native American or Alaskan Native: the only group with positive neg_inertia -> tend to stay in negative states longer
- Black/African American: the only group with pos_inertia -> tend to stay in positive states longer (which is unexpected)
- White/Caucasian: the only group with negative inertia across all three emotions -> tend to bounce back quickly overall (emotionally adaptive).
 - This may reflect greater access to resources, social safety nets, and less exposure to systemic stressors for White people.
- Both "Other" and "Decline to state" have much higher aro_inertia than others.
 - This may suggest that the people who are less confident or more confused about their identities are likely to face heightened stress, social vigilance, or lack of belonging–all known to elevate arousal.

```

Correlation Among Emotional Inertia Types

 pos_inertia and neg_inertia have moderate positive correlation: people who tend to hold onto positive emotions also tend to hold onto negative emotions, suggesting emotional stickiness • aro_inertia and neg_inertia have small-to-moderate positive correlation: those who hold onto negative emotions also tend to stay aroused longer

0.4 Manova: inertia types by sex

How different inertia types (pos inertia, neg inertia, aro inertia) vary by sex?

```
manova_model <- manova(cbind(pos_inertia, neg_inertia, aro_inertia) ~ sex, data = inertia_full
summary(manova_model, test = "Wilks")</pre>
```

```
## Df Wilks approx F num Df den Df Pr(>F)
## sex 2 0.95394 1.2009 6 302 0.3056
## Residuals 153
```

- Wilks' Lambda = 0.954 -> near 1, meaning the difference is small
- P-value = 0.3056, which is not significant
- Conclusion: the difference of pos_inertia, neg_inertia, aro_inertia between sex is not significant

Test each inertia type separately:

```
summary.aov(manova_model)
```

```
Response pos_inertia :

```

- Positive inertia (0.200) and negative inertia (0.202) are about the same. Negative is slightly higher than positive.
- Arousal inertia (0.329) is much higher than the other two, meaning that arousal emotion is likely to persist.

0.5.2 Cross-lag paths (how one emotion affect another at the next time point)

```
model_clpm <- '
    # Autoregressive (inertia) paths

- Arousal inertia (0.414) is much higher than positive inertia (0.137) and negative inertia (0.143)
- Ipos ~ Ineg_lag1 (0.165): negative emotion predicts positive emotion in the next moment, which might reflect emotional rebound
- Ineg \sim Ipos_lag1 (0.173): positive emotion enhances negative emotion in the next moment, which might reflect emotional mix or trial order effect
- Iaro ~ Ipos_lag1 (-0.043): positive emotion decreases arousal at the later stage
- Iaro ~ Ineg lag1 (-0.063): negative emotion decreases arousal at the later stage
- Ipos ~ Iaro lag1 and Ineg ~ Iaro lag1 are not significant
- Conclusion:
 - Both positive and negative emotions predict more of the opposite in the next moment
 possibly due to Emotion regulation attempts, Rebound effects, and Task structure
 - Arousal is influenced negatively by both positive and negative emotions maybe a sign of emotional resolution or recovery
